Resumo

Este estudo analisa a capacidade dos *Exchange-Traded Funds* (ETFs) em replicar três dos mais conhecidos índices accionistas: FTSE 100, DJ Eurostoxx 50 e S&P 500.

Os resultados mostram que os ETFs que replicam proporcionalmente os índices acima descritos apresentam valores relativos ao alfa positivos, embora dificilmente estes sejam estatisticamente significativos, enquanto os ETFs que replicam de forma alavancada e inversa os mesmos índices accionistas apresentam alfas negativos, embora não estatisticamente significativos. Os ETFs que replicam o S&P 500 fazem-no de forma mais precisa do que os ETFs que replicam o Eurostoxx 50 ou o FTSE 100. Os ETFs que replicam proporcionalmente o Eurostoxx 50 parecem evidenciar maior dificuldade em replicar o índice de referência. Os betas apresentam uma dispersão elevada, sobretudo para os ETFs que replicam o FTSE 100 e o Eurostoxx 50, o que implica que os valores de *Tracking Error* sejam igualmente dispersos.

Os ETFs que replicam proporcionalmente o FTSE 100 tendem a negociar a prémio enquanto os ETFs que replicam proporcionalmente o Eurostoxx 50 tendem a negociar a desconto. Os ETFs que replicam de forma alavancada e inversa um índice tendem a negociar a prémio. Os Betas e os *Tracking Errors* não são consistentes ao longo do tempo.

No final do estudo, é comparada a capacidade demonstrada pelos ETFs em replicar um determinado índice com a capacidade demonstrada por Fundos de Investimento tradicionais em replicar o mesmo índice. Conclui-se que, em geral, os ETFs tendem a replicar melhor um determinado índice do que os Fundos de Investimento tradicionais.

Palavras-Chave: *Exchange-Traded Funds, Capacidade de replicar índices, Tracking Error, Fundos de Investimento*

Abstract

This work analyses the mimicking abilities of Exchange-Traded Funds (ETFs) that track three well-known stock market Indexes: the FTSE 100, DJ Eurostoxx 50 and the S&P 500.

The results show that equity index ETFs present positive alphas, although hardly s.s., while leveraged and inverse ETFs present negative alphas although not statistically significant. ETFs that track the S&P 500 index, do it more precisely than ETFs that track Eurostoxx 50 and FTSE 100 index. The equity index ETFs that track the Eurostoxx 50 seems to be the worst into track their benchmark. Betas present a large dispersion mainly for FTSE 100 and Eurostoxx 50 ETFs' which implies that tracking errors are also larger for these ETFs.

Equity index ETFs that track the performance of the FTSE 100 index tend to be traded at a premium and equity index ETFs that track the performance of Eurostoxx 50 index at a discount. Leveraged and inverse ETFs tend to be traded at a premium. Beta and tracking errors are not consistent over time.

On the final of the paper I compare the tracking abilities of ETFs with indexed mutual funds. I find that, on general, ETFs tend to track better the benchmark than Traditional mutual funds.

Keywords: *Exchange-Traded Funds, Tracking ability, Tracking Error, Mutual Funds*

Acknowledgment

I express my acknowledgment to everyone that helps me in the elaboration of this master thesis.

To professor and supervisor Sofia Brito Ramos for the support that gave me during the design of this study.

To my fathers and my girlfriend for the patience and comprehension demonstrated during the last couple of months, I express, sincerely, my grateful.

To João Lampreia, head of Research department at Banco de Investimento Global (Banco BiG), bank where I am currently working for, for the support and flexibility that he always demonstrate since my first day in his department, which was essential to the design of this master thesis.

Sumário Executivo

Desde o seu aparecimento, os *Exchange-Traded Funds* cativaram não só os investidores, pela forma como criaram um novo veículo de investimento que possibilita, de forma simples, diversificar um portefólio, mas também a classe académica, que cedo começou a explorar esta nova forma de investimento, suas características, vantagens e eficiência. No primeiro ponto deste estudo, procurou-se descrever a evolução que este produto financeiro tem experimentado ao longo dos últimos anos.

No segundo ponto, e no seguimento do interesse gerado em torno dos *Exchange-Traded Funds*, habitualmente designados ETFs, este estudo pretendeu investigar a capacidade evidenciada pelos ETFs em replicar três dos mais conhecidos índices accionistas: FTSE 100, Eurostoxx 50 e S&P 500. No estudo foram incluídos não só ETFs que replicam na mesma proporção o seu *benchmark* mas também os que replicam de forma alavancada e inversa a *performance* de um índice. Assim, procurou-se avaliar a magnitude do alfa e do beta para cada um dos ETFs em análise, através de uma regressão linear onde a variável depende é o ETF em estudo e a variável explicativa é o seu *benchmark*. De seguida, estudou-se igualmente o desvio médio do retorno de cada ETF relativamente ao retorno do seu *benchmark*, através do cálculo do *Tracking Error*. Seguindo os estudos anteriormente realizados por Ackert e Tian (2000), Elton et al (2002) e Lin e Chou (2006), procurou-se adicionalmente analisar se os ETFs negoceiam a prémio ou a desconto relativamente ao seu *Net Asset Value* (NAV). Por fim, estudou-se a consistência dos alfas, betas e *Tracking Error* ao longo do tempo.

O último ponto do estudo centrou-se numa abordagem comparativa, onde se procurou relacionar a capacidade dos ETFs em replicar o seu *benchmark* com a capacidade dos Fundos de Investimento tradicionais em replicar o mesmo *benchmark*, sendo que para tal foram igualmente aplicados os processos relativos às regressões lineares e *Tracking Error*.

Os resultados mostraram que os ETFs que replicam proporcionalmente os índices anteriormente descritos apresentam valores relativos ao alfa positivos, embora tendencialmente não sejam estatisticamente significativos, enquanto os ETFs que replicam de forma alavancada e inversa os mesmos índices accionistas apresentam alfas negativos, igualmente não estatisticamente

significativos. Adicionalmente, foi possível observar que os ETFs que replicam o índice S&P 500, fazem-no, geralmente, de forma mais precisa do que os ETFs que replicam o índice Eurostoxx 50 ou o FTSE 100. Os ETFs que replicam proporcionalmente o Eurostoxx 50 parecem evidenciar maior dificuldade em replicar o índice de referência. Os betas apresentam uma dispersão elevada, sobretudo para os ETFs que replicam o índice FTSE 100 e o índice Eurostoxx 50, o que implica que os valores de *Tracking Error* sejam igualmente dispersos.

Os Betas e os *Tracking Errors* não se apresentam consistentes ao longo do tempo, demonstrando mesmo, em alguns casos, desvios consideráveis. Os ETFs que replicam proporcionalmente o índice FTSE 100 tendem a negociar a prémio enquanto os ETFs que replicam proporcionalmente o índice Eurostoxx 50 tendem a negociar a desconto. Os ETFs que replicam de forma alavancada e inversa um índice tendem a negociar a prémio.

Relativamente ao último ponto, concluiu-se que, em geral, os ETFs tendem a replicar melhor um determinado índice do que os Fundos de Investimento tradicionais.

I. Introduction

Holding the market portfolio is one of milestones of the modern finance theory. The attempts to trade large portfolios in a single transaction started in late 1970s and early 1980s with a program trading that was able to trade often a portfolio with 500 stocks like the S&P 500 index, with a single order placed at a major brokerage firm. The Exchange-Traded Funds' (ETFs) history starts in 1989 with Index Participation Shares (IPS), a proxy for the S&P 500 traded on the American Stock Exchange (AMEX) and Philadelphia Stock Exchange (FSE). More similar to futures contracts than the current form ETFs, the new financial instrument draw the attention of market participants. It was settled on cash and tracked the benchmark index very closely. The increasing popularity of the new financial vehicle threatened futures trading, pressing the U.S. Securities and Exchange Commission (SEC), which approved the product before, to force the AMEX and the FSE to stop the sales of the product in the US Market.¹

A few months later, a similar product, the Toronto Index Participation Shares (TIPS), was launched on the Toronto Stock Exchange (TSE). The TIPS were a warehouse receipt-based instrument designed to track the TSE 35 and TSE 100. TIPS traded actively and attracted a substantial cash-flow from Canadian and international investors. The success of those financial products, led the AMEX to try again, and develop a product that could satisfy SEC regulation in the US market.

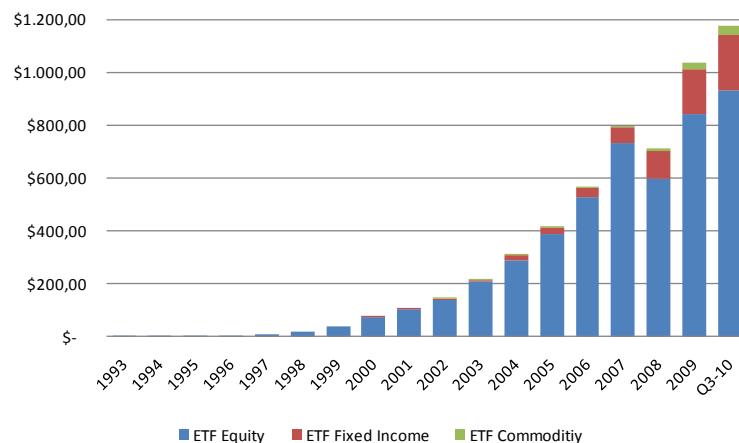

In 1992, the AMEX request the first authorized stand-alone index based Exchange-Traded Fund (ETF). That petition was approved and in January 1993 appeared the S&P Depository Receipts Trust Series 1, known as SPDR. SPDR tracks the performance of the S&P 500 index and became the first commercial successful ETF. Later on, other ETFs have been launched to track other well-known US indexes such as the Nasdaq and Dow Jones Industrial Average.

¹ Wiandt, J., and McClachy, W., 2002, *Exchange Traded Funds: An Insider's Guide to Buying the Market*. Index Funds.

After the success of ETFs in the US market, the 2000's are marked by the introduction of ETFs in Europe and Asia (iShares launched, on April 2000, the first ETF to track the performance of the Eurostoxx 50).²

The industry of ETFs has experienced a significant growth, the data from the 3Q10 shows that there are 2379 ETFs, representing USD 1181.3 bn, from 129 providers on 45 exchanges around the world. The growing importance of ETFs is expressed by the numbers of the first 9 months of 2010, where the Assets Under Management (AUM) increased by 14%, the number of ETFs by 22.3% and the ETF's average trading volumes by 14.7%. Besides the innovations introduced by ETF's industry, this new financial product started to capture market share to the traditional mutual funds, which in the first 7 months of 2010 registered a decrease on net sales value by USD 221 bn, while net sales of ETFs increased by USD 81,6 bn.³

Figure II
Evolution of AUM and number of ETFs since 1993 until 3Q10

Source: BlackRock

On figures I and II, we can observe the exponential growth of ETF, in terms of both number and AUM. We can also see the growth of other classes of ETFs like Fixed Income and Commodity ETFs.

The most significant innovation that ETFs brought to us was the possibility of an investor to have access to a pool of securities with only a single vehicle, identical to traditional mutual funds, with the advantage of trading like shares that can be bought and sold throughout the trading session on a securities exchange through a broker-dealer. If in early days ETFs were traded mostly by institutional investors for use in sophisticated trading strategies like hedging, today the demand for ETFs by non-institutional investors is quite significant, which was helped by the growing ability of individuals to access financial information or advise, that gave them the ability to invest in products about which they might not have been previously aware.

This work will evaluate the mimicking abilities of ETFs, i.e., the capacity of a specific ETF into track the performance of its benchmark. The focus on equity index ETFs was motivated by the history of ETFs, where ETFs were created with the goal of coping a certain market index. Nowadays there is a wide range of styles (besides market index ETFs we have Commodity, Fixed-Income and Currency ETFs) but equity index ETFs also present advantages like longer history and more liquidity.

Differently from previous works, I study also leveraged and inverse ETFs besides equity index ETFs, due to the significant importance that this specific financial product has assumed over the last years.

On a second part, I cross the previous results with the liquidity of the last 6 month of trading, the values of the fees and the tracking error result for each ETF. This additional analysis try to understand if exist a relation among those parameters and the tracking capacity of the ETFs.

The last objective will be compare the result of the ETFs analysis' with traditional mutual funds, too see if a much recent investment vehicle like ETFs is so efficient as the traditional mutual funds into track the benchmark's performance.

II. Literature Review

The first academic studies on ETFs appeared in the end of the 90's motivated by the high degree of acceptance of the product among investors. The researchers began studying not only the ETF as a specific investment vehicle but also began comparing them with traditional mutual funds.

Gastineau (2001) discusses some of the advantages and innovations brought by ETFs, the low expense ratios of ETFs and how ETFs manage to avoid significant capital gains contributions. Dellva (2001) describes how the redemption processes provide the ETFs with significant tax efficiencies and finds that tax deferred, long-term retirement investors have little or no advantage from using ETFs as opposed to traditional mutual funds. Fuhr (2001) points out that ETFs' characteristics make them a viable alternative to trading futures for investors looking to increase or reduce their exposure to countries, sectors, industries, and styles. ETFs allow investors the flexibility to use them for numerous applications, which can be appealing to both individual and institutional investors.

Dellva (2001) applies a cost comparison among the primary trackers of S&P 500 Index, SPDRs and Barclays' iShares S&P from the bundle of ETFs and the Vanguard index mutual fund. The results shows that transaction costs limit ETF attractiveness for small investors. The in-kind creation and redemption process of ETFs provide significant tax efficiencies. Finally, the study

finds little or no ETF advantage for the tax deferred, long-term retirement investor. Poterba and Shoven (2002) compare the pre-tax and after-tax returns on the largest ETF, the SPDR trust and Vanguard Index 500, which both track the S&P 500 Index, concluding that these funds substantially present the same performance, and in a more precise view, the after-tax and the pre-tax returns on the fund were slightly greater than those on the ETF. Gastineau (2004) suggests that the pre-tax performance of benchmark index ETFs is usually lagging than the index mutual funds which use the same indexes. He justifies that low return with the lack of aggressiveness for a portion of ETFs managers and with the process of ETFs creation and redemption that restricts managers' ability to follow accurately, immediately and inexpensively the adjustments of the tracking indexes. Also Miffre (2004) list some advantages of ETFs over the traditional mutual funds. More recently, Svetina and Wahal (2008) found that the majority of ETFs that track indexes do not have a corresponding index mutual fund and when they have a real competitor mutual fund they usually deliver a slightly better performance.

The performance of ETFs and how well they track the benchmark was also an issue of interest among the academic research. Frino and Gallagher (2001) pointed the inevitability of tracking error in index fund performance due to market frictions. The authors highlight the difficulties faced by index funds and showed that S&P 500 index funds, on average, outperformed active funds after expenses over the sample period. Elton et al (2002), document that the SPDR underperforms both its underlying index and conventional S&P 500 index funds. Rompotis (2005) examines the performance of 16 ETFs and index funds in pairs tracking the same index, and reports that they substantially produce similar returns and tracking errors. Gallagher and Segara (2005) investigate the ability of the Index ETF into track the performance of the Australian Stock Exchange, showing that ETFs track efficiently the underlying benchmark before costs, have lower tracking errors than index managed funds and difference between trading price and NAV is small and not occur with frequency. Milonas and Rompotis (2006) examine the performance and the trading characteristics of a sample of 36 Swiss ETFs. They find that Swiss ETFs underperform their benchmark indexes while having investors exposed to greater risk.

Another issue investigated is whether ETFs are traded at premium or discount, i.e., ETFs trading price relative to their NAV. Ackert and Tian (2008) examined pricing in the market for SPDR's, showing that they do not trade at economically significant discounts, unlike closed-end mutual funds. The same conclusion is not also applicable to MidCap SPDRs that report a larger economically significant discount. Delcoure and Zhong (2007) concluded that iShares ETFs trade at economically significant premiums even controlling the transaction costs and time-zone measurement errors. However, they showed after that the deviations of most iShares' price and NAV are not persistent and tend to zero within two days. Also Jares and Lavin (2004), show that the non overlapping of ETFs that trade on US exchanges but provide exposure to foreign markets, in this case iShares ETFs that are exposed to Japan and Honk-Kong markets, increase the existence of discrepancy among price and NAV. Elton et al (2002) studied the deviation of trading price from NAV, proving that this difference is negligible due to the ability of investors to create or delete Spiders at the end of every trading day.

III. Data

This paper focuses on equity index ETFs that track three major stock market indexes: S&P500, EUROSTOXX 50 and FTSE 100. From Datastream, I identified several ETFs that track those indexes. I chose both equity index ETFs as well as leveraged and inverse ETFs, where the latter also mimic an equity index but have a multiplier like -1 or 2.

To avoid currency issues, I chose ETFs that are quoted on the same currency as the benchmark.

The Bloomberg's ticker of the ETF identifies the ETF and the exchange where it is traded. This means that the same ETF can be traded in different exchanges. Therefore, I eliminated ETFs that are repeated, i.e., that are quoted on different markets (stock exchanges) by choosing the same market as the benchmark index, with the exception of ETFs that track the Eurostoxx 50, which are a special case. Thus, ETFs that track FTSE 100 index have LN on Bloomberg's ticker, that correspond to a product that trade on London Stock Exchange and the ETFs that track S&P 500 have always US designation, which represent ETFs that are traded on the US market. For ETFs that track Eurostoxx 50 index, like the index contain the 50th shares with the highest

capitalization from different European indexes, we have ETFs that are traded on different stock exchanges like FP and NA, which means that the ETF is traded on Euronext Paris and on Euronext Amsterdam, GY which means that the ETF is traded on Deutsche Börse (Xetra) and SM which means that the ETF is traded on Madrid Stock Exchange.

From Lipper, I selected index mutual funds whose benchmark was also the selected stock market indexes: S&P500, EUROSTOXX 50 and FTSE 100.

Daily prices and net asset values of the ETFs and mutual funds were taken from Bloomberg as well as additional information such as currency, inception date and fees.

One problem that I faced on the construction of the database was the different lifetime of ETFs (some are very recent), which led to a different number of observation among the ETFs.

The final sample has 20 indexing ETFs and 16 Leveraged ETFs. More specifically, the final database includes 5 equity index ETFs and 3 leveraged and inverse that track the performance of FTSE 100, 13 equity index ETFs and 6 leveraged and inverse ETFs that track the performance of Eurostoxx 50 and 2 equity index ETFs and 7 leveraged and inverse ETFs that track the performance of S&P 500.⁴ Notice that the sample size in other studies has varied from one fund to twenty. For instance, Poterba and Shoven (2002) and Elton et al (2002) focus on one ETF (SPDR) while Jares and Lavin (2004) examine two funds (iShares Japan and Hong Kong funds) or even Delcoure and Zhong (2007) study 20 international ETFs traded on US exchanges.

By company, we can find the biggest ETFs' providers as BlackRock through the iShares, State Street Global Advisors through SPDR, Deutsche Bank through db x-trackers and Lyxor Asset Management through Lyxor ETFs.

⁴ See annex I, II and III for ETFs' summary statistics

On table I, on the first column we have the name of the equity index ETFs, on the second the issuer and on the third column the Bloomberg's Ticker. The fourth column represents the benchmark. We see that the final sample has 5 equity index ETFs that track the FTSE 100, 13 that track the Eurostoxx 50 and 2 that track the S&P 500. On column five we can confirm that all equity index ETFs traded in the same currency as the benchmark. Regarding the inception date we can see that equity index ETFs that track S&P 500 have the oldest inception date, which it is not a surprise considering the history of the ETFs. The next column presents the number of observations that, as we can see, varies considerably among the equity index ETFs. Despite the efforts, it was not possible to collect expenses ratios for all ETFs due to the lack of information regarding fees. It is also presented the average trading volume in the last 6 months and the current capitalization of the equity index ETFs. These two last features confirm that SPDR, also known as the Spyder, is the largest ETF in the world. An interesting point is the more

discrepancy observed among the average volume of the last 6 month that occurs on equity index ETFs with less competitors, equity index ETFs that track S&P 500 and FTSE 100, which is justified by the concentration of the demand for ETFs.

Table II shows the sample characteristics of leveraged and inverse ETFs, starting by the name and the issuer. The style is described on column (3). Basically, some funds track the index in the same direction (long) others in the opposite (short), where the level of leverage is given by the multiplier. The range of multipliers goes from 1 to 3. Three ETFs track the FTSE 100, six the Eurostoxx 50 and seven the S&P 500. We have more leveraged and inverse ETFs that track the S&P 500 than equity index ETFs that track the same index, which is justified by the more competitiveness among the providers on leveraged and inverse ETFs, which is not seen on equity index ETFs due to the position that SPDR assumes in the market. Leveraged and inverse ETFs were launched more recently, the oldest is from July 2006, which led to a smaller number of observations when comparing with equity index ETFs. Fees are larger for leveraged and inverse ETFs, which is reasonable considering the complexity of tracking leveraged and inversely the

performance of an index. Finally, I highlight that the leveraged and inverse ETFs that track the performance of the S&P 500 index have, in average, a much significant volume than the other leveraged and inverse ETFs due to the larger demand for S&P 500 related products.

IV. Empirical Results

(i) Tracking Abilities

In this section, I start by evaluate the capacity of the ETFs into track the performance of the benchmark index. For that, I first compute the daily returns of the ETFs by applying the following equation (I):

$$R_t = \frac{Price_t}{Price_{t-1}} - 1 \quad (\text{I})$$

Where, R_t refers to the percentage return of ETF on day t, $Price_t$ refers to the trading price of ETF on day t and $Price_{t-1}$ refers to the trading price of ETF on day t-1.

Then, I use the following regression (Equation II):

$$R_{i,t}^{ETF} = \alpha_i + \beta_i R_t^{Benchmark} + \varepsilon_t \quad (\text{II})$$

Where $R_{i,t}^{ETF}$, is the daily return of ETF i on day t and $R_t^{Benchmark}$ refers to the percentage return of Benchmark on day t. The alpha, α , is the constant of the model and Beta, β , represents the capacity of the ETF into track the performance of the benchmark as they propose itself to do.

I start by analyze the equity index ETFs. Our expectation is that, since they copy the benchmark, $\beta_i = 1$ and $\alpha_i=0$, as well as the R^2 be high. Therefore, these two hypotheses will be tested.

On Table III, we can see the results of the time-series regression for each equity index ETF. The alpha assumes a small positive value for commonplace equity index ETFs and it is only statistically significant with 95% confidence level for one ETF. Regarding the beta, it tends to be close to 1 in the majority of the cases, however, on CS ETF EURO STOXX 50 and UBSETF BB E STOXX 50 the beta is abnormally low. The R^2 shows that almost all equity index ETFs in this analysis are fully invested on the benchmark index constituents. Finally, the F-Test shows that

only HSBC FTSE 100 ETF on FTSE 100 benchmark index and SPDR S&P 500 ETF TST on S&P 500 benchmark index do not reject the null hypothesis, showing that the beta of those ETFs are equal to one. However, three ETFs reject the null hypothesis on Eurostoxx 50 benchmark index, HSBC EURO STOXX 50, ISHARES DJ (FRA) EUROSTOXX 50 and ISHARES DJ ES50.

On table IV, we can see the results of the time-series regression for each leveraged and inverse equity index ETF.

Contrary to equity index ETFs, the alpha tends to be negative although not statistically significant. The betas tend to be close to the goal they proposal. However, we can see, by

analysing the result of the F-Test, that leveraged and inverse ETFs that track the S&P 500, track worse its benchmark than leveraged and inverse ETFs that track others benchmarks. The F-Test, on table V, shows that any leveraged and inverse ETF that track the S&P 500 index reject the null hypothesis, contrary to equity index ETFs. Finally, the R² shows that almost all ETFs, excluding DB X-TRACKERS FTSE 100 SH DA, are fully invested on the benchmark index constituents, according to the specific strategy of each leveraged and inverse ETF.

(ii) Tracking Errors

As, for instance, Frino and Gallagher (2001), Rompotis (2005), and Gallagher and Segara (2005) did, I compute the tracking error (TE) value for each equity index and leveraged and inverse ETF. The literature presents several measures to compute the tracking error of the ETFs, which represents the deviation of the performance of the ETF from the performance of the corresponding benchmark index.

The first method computes the tracking error by calculating the average of absolute differences between the returns of ETFs and the corresponding benchmark index (Equation III):

$$TE_1 = \frac{\sum_{t=1}^n |R_{ETF_t} - R_{Benchmark_t}|}{n} \quad (\text{III})$$

Where R_{ETF_t} represents the return of ETF on day t and $R_{Benchmark_t}$ represents the return of its benchmark on the same day t.

The second method to computes the standard deviation of return differences between ETFs and their benchmark over n days (Equation IV):

$$TE_2 = \sqrt{\frac{\sum_{t=1}^n [(R_{ETF_t} - R_{Benchmark_t}) - (\bar{R}_{ETF} - \bar{R}_{Benchmark})]^2}{n-1}} \quad (\text{IV})$$

Where R_{ETF} represents the return of ETF and $R_{Benchmark}$ represents the return of its benchmark.

The last method computes the tracking error using the standard error of the regression computed previously (Equation II).

Finally, and to reinforce the analysis, I also compute the semi tracking error, where the standard deviation is only computed for the times the ETF does not beat the benchmark (Equation V):

$$S - TE = \sqrt{\frac{\sum_{n=1}^N \text{Min}(\{R_{ETF} - R_{Benchmark}\}, 0)^2}{N}} \quad (\text{V})$$

To make easy the interpretation, I annualized all daily tracking errors by using the following equation (Equation VI):⁵

$$TE_{Annual}A = TE_{Daily}250^{0.5} \quad (\text{VI})$$

Table VI presents the results of the tracking errors and semi-tracking error, for each equity index ETF.

We can conclude that, in general, equity index ETFs that track the S&P 500 index, do it more precisely than equity index ETFs that track Eurostoxx 50 and FTSE 100 index. The equity index ETFs that mimic the Eurostoxx 50 seems to be the worst into track their benchmark.

Notice that, tracking errors vary considerably. For instance for those who track FTSE 100 it goes from 1.26% to 12.14%, while for ETFs that track the Eurostoxx 50 vary from 2.15% to 22.03%.

On Table VII, we have the results of the tracking error and semi-tracking error, for each leveraged and inverse ETF. We can see that the values obtained are generally larger than the values obtained by the equity index ETFs, which is an expected result due to the complexity of leveraged and inverse strategies. The conclusions seem to be similar, since the leveraged and inverse ETFs that track the S&P 500 track better their benchmark.

(iii) Premium/discount analysis

Following Ackert and Tian (2000), Elton et al (2002) and Lin and Chou (2006), I try to analyze if the ETFs' price traded at a premium or at a discount relatively to their NAV. To compute that, I use the formula below (Equation VII):

$$\alpha_t = \frac{Price_t - NAV_t}{NAV_t} \quad (VII)$$

Where the α_t counts for the deviation of the price relatively to the benchmark. If $\alpha_t > 0$ the ETF trades at a premium on day t, if $\alpha_t < 0$ the ETF trades at a discount on day t.

However, in my analysis, I use the average of α_t for each ETF, by summing N α_t and dividing the result by N. See equation VIII.

$$\bar{\alpha} = \frac{\sum_{t=1}^n \alpha_t}{n} \quad (VIII)$$

On table VIII, we can see if the equity index ETF is trading at a premium or a discount, i.e., how the price of ETF tracks the corresponding NAV. We can conclude that the equity index ETFs that track the FTSE 100 traded most of the time at a premium, while the equity index ETFs that have the Eurostoxx 50 as a benchmark traded generally at a discount. For the equity index ETFs that track the S&P 500, we cannot make a real analysis due to the reduce number of the sample that we have.

Table VIII

(iv) Time Consistency of Tracking abilities

In this section, I try to understand the evolution of the alpha, beta and tracking error for each equity linear ETF in the time frame in analysis. I compute alpha, beta and the tracking errors using moving windows of 60 observations. Because I am interesting in the mimicking abilities of the ETFs I use the NAV of the ETFs in this analysis.

So, on the figures below (Figure III, IV, V, VI, VII and VIII), we can see the value of the alpha and beta for each ETF, grouped into benchmarks. We can see that the alpha of equity index ETFs that track the Eurostoxx 50 are, in average, more volatile than the equity index ETFs that track the FTSE 100 and S&P 500. Additionally, the evolution of the beta shows again that, equity index ETFs that track the Eurostoxx 50 have, in average, more difficult into track its benchmark than the equity index ETFs that track other benchmarks.

Figure III
Evolution of the alpha of equity index ETFs that track the FTSE 100

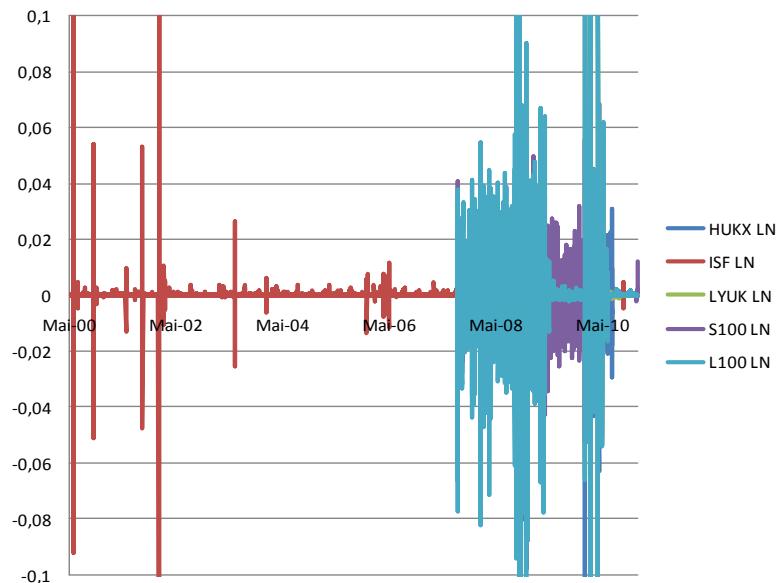

Figure IV
Evolution of the alpha of equity index ETFs that track the Eurostoxx 50

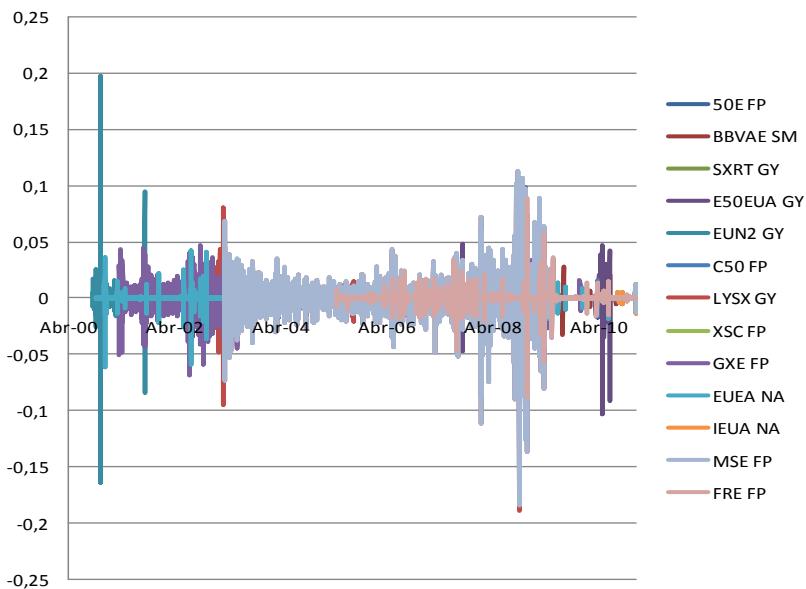

Figure V

Evolution of the alpha of equity index ETFs that track the S&P 500

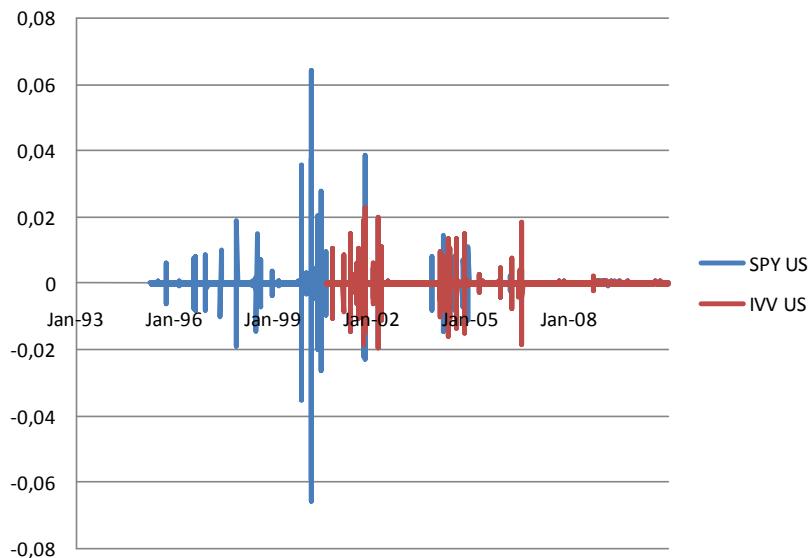

Figure VI

Evolution of the beta of equity index ETFs that track the FTSE 100

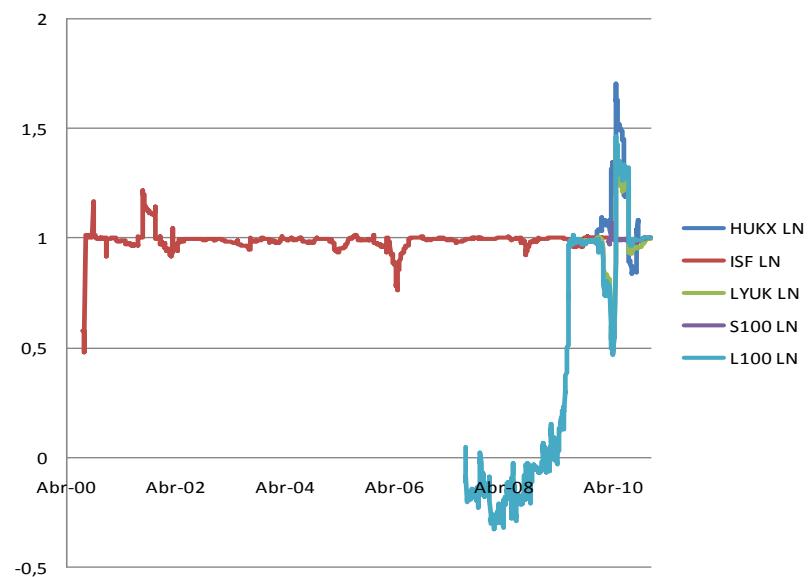

Figure VII
Evolution of the beta of equity index ETFs that track the Eurostoxx 50

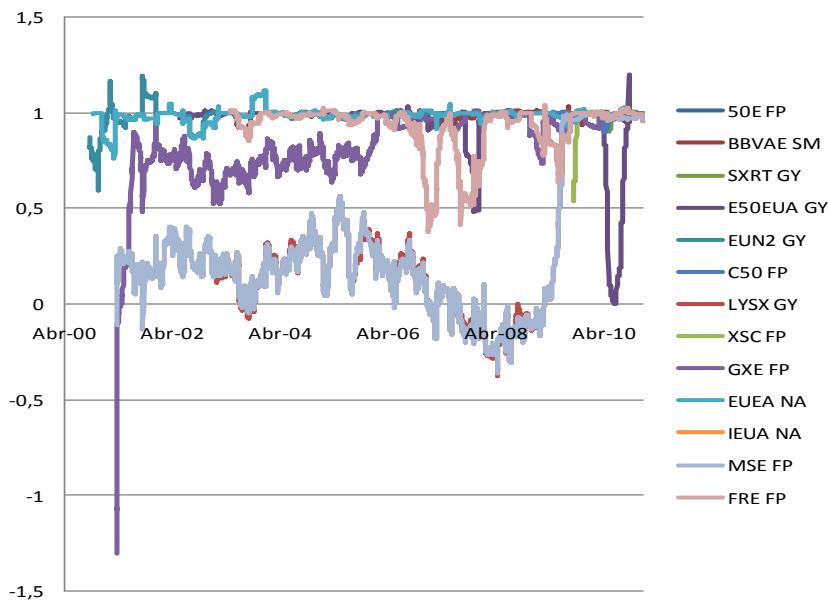

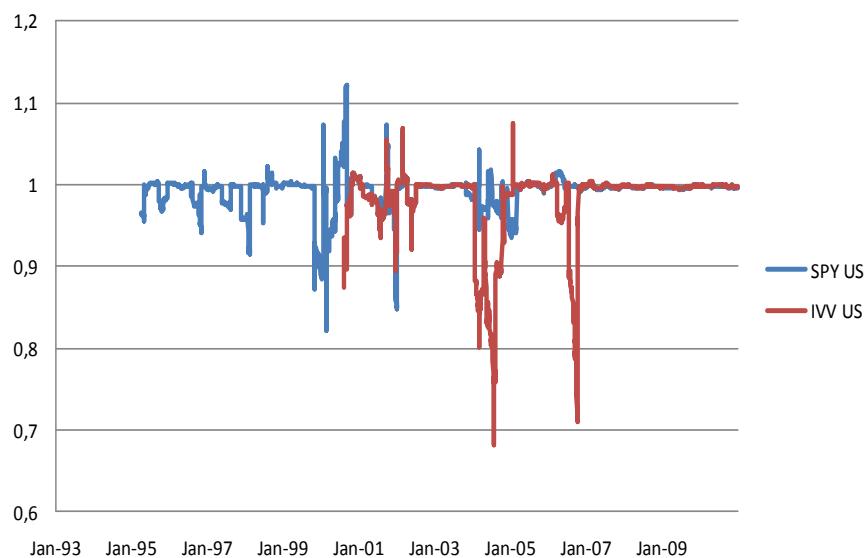

Figure VIII
Evolution of the beta of equity index ETFs that track the S&P 500

On figures IX, X and XI, we can see the value of the tracking error (computed by the second method) for each equity index ETF, from the three benchmarks, during the time frame in analysis. We can see that the tracking errors of ETFs that track the Eurostoxx 50 assume, in

average, a higher value, so, a high divergence with the benchmark. Again, the ETFs that track the S&P 500 present a higher capacity into track the performance of their benchmark.

Figure IX
Evolution of the TE of equity index ETFs that track the FTSE 100

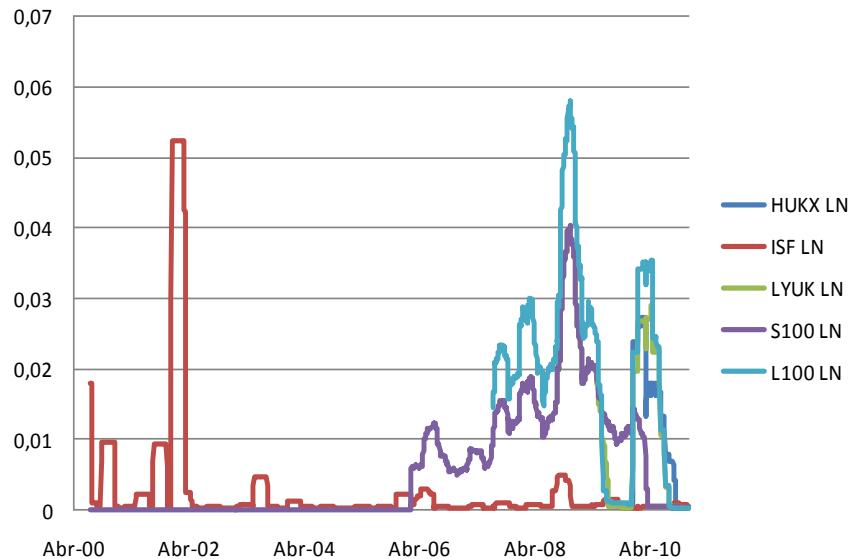

Figure X
Evolution of the TE of equity index ETFs that track the Eurostoxx 50

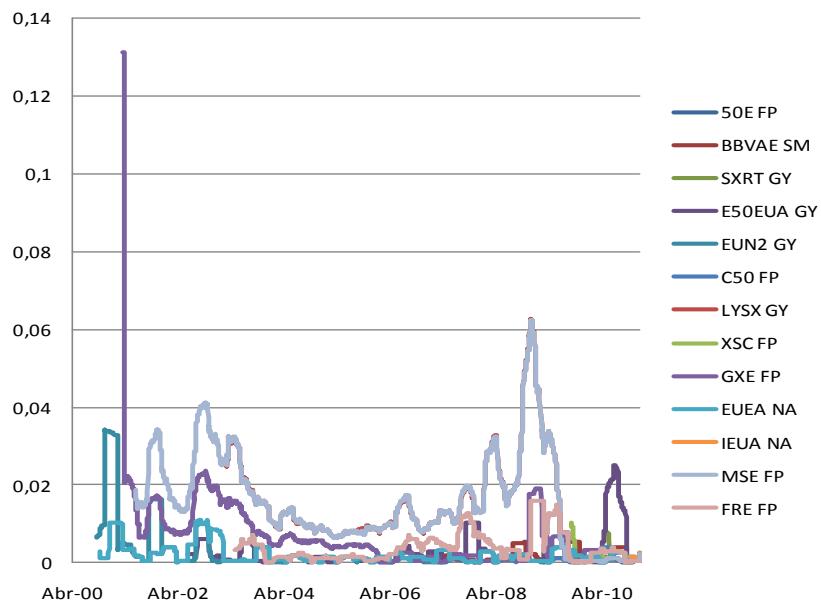

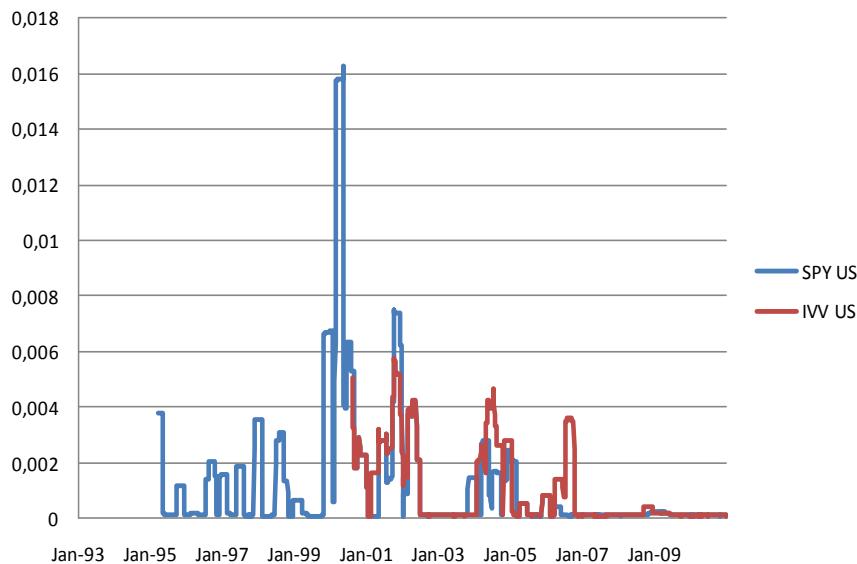

Figure XI
Evolution of the TE of equity index ETFs that track the S&P 500

(v) Main conclusions

Equity index ETFs

Linking the information regarding equity index ETFs, we can see that there is no parallelism between the number of observations, which is obviously related with the inception date, and the value of the beta for each equity index ETF. So, in this case, it is not true that usually the ETFs that have oldest inception date are the same that have the larger tracking capacity, i.e., that have the beta closer to 1. Additionally, the average volume of the last 6 month is not explained by the beta of the ETF, i.e., the average volume is not explained by the tracking ability of the ETF. The same conclusion can be applied to the fees, since fees are not explained by the tracking ability of the ETF. Thus, an ETF with a highest fee is not always the same that has the highest tracking capacity. Finally, we can see that the relation between beta and tracking error is not linear, the ETFs with low tracking errors are not always the ETFs that have a beta closer to 1. However, the ETFs that reject the null hypothesis on the F-Test are usually the same that have a beta closer to 1 and lower TE.

In sum, to choose an ETF, the investor should decided what feature he considers to be the most important one, which feature makes an ETF preferable to the other that track the same index, that have the same benchmark.

Leveraged and inverse ETFs

In a cross analysis, we can see a relation among the average volume, tracking error and beta on two ETFs that tracks 2 times the performance of the S&P 500, where the ETF with the highest average volume is the same with the lowest tracking error and with the beta closer to 2. However, on the ETFs that track 2x the performance of the Eurostoxx 50, the same conclusion is not applicable. On ETFs that track 2x the inverse of the S&P 500 index, we can see through the average volume, tracking error and beta that, again, the ETF with the highest volume, is the same with the lowest tracking error and beta closer to -2, while on the ETFs that track 2x the inverse of the Eurostoxx 50 index, we cannot see that relation.

(vi) Comparison with Mutual Funds

Mutual Funds

For mutual funds, after extracting from Lipper a series of mutual funds information, I restricted the provisional database by filtering some of them. I started by choosing only open-end indexed mutual funds, and by eliminating ETFs that possibility could be among the information extracted. Then, I selected only mutual funds that are primary flag and that declare as having as benchmark the FTSE 100, Eurostoxx 50 and the S&P 500. Finally, and to complete the process, I chose only mutual funds with an ISIN code, in order to extract the additional data from Bloomberg. Notice that, in the final I organized mutual funds in three sets, since each set account for one benchmark index, as I did for ETFs.

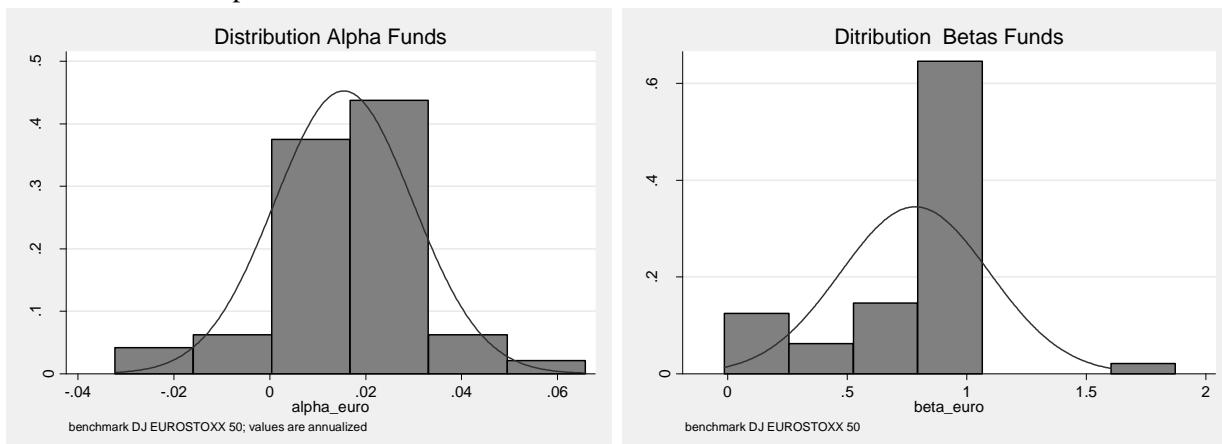

On annex IV, V and VI, I present the summary statistics and on annex VII, VIII and IX, I present the detailed information about the of my final database. We can see that mutual funds, that track the S&P 500 index, have the largest number of observations and the largest sample (number of

mutual funds). Mutual funds that track the FTSE 100 index present more observations than the mutual funds that track the Eurostoxx 50 index, while in terms of ETFs' sample, we have the opposite. Additionally, by making a simple average of the information about the fees for each benchmark mutual funds, we can conclude that, the mutual funds that track the performance of S&P 500 present, in average, the lowest fees, while the mutual funds that track the performance of Eurostoxx 50 present, in average, the highest fees.

On annex X, we can see the results of the time-series regression for the set of Mutual Fund that track the performance of the Eurostoxx 50 index. The alpha assumes a small value for commonplace mutual funds and there is only statistically significant with 95% confidence level for one mutual fund, ING Direct Fondo Naranja Euro Stoxx 50, FI. The average Beta rounds 0.8, which shows that, in average, mutual funds have not significant deviations from the benchmark. Among all the observations, only two Betas are not statistically significant, the Argenta actions UEM and Euro Indicel LCF (see also Figure XII).

Figure XII

Distribution of Alpha and Beta values for Mutual Funds that have the Eurostoxx 50 as the benchmark

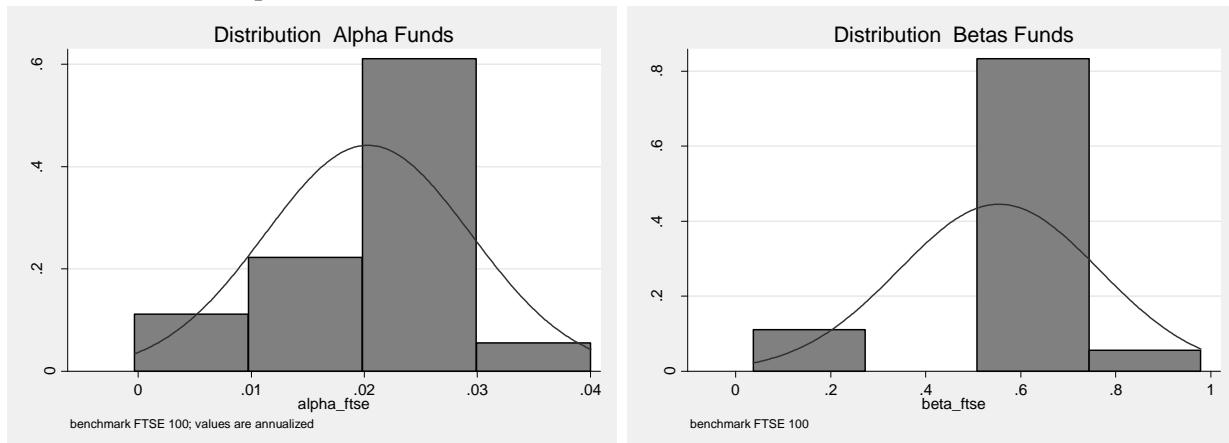

Annex XI shows the same information as annex X but for mutual funds that track the performance of FTSE 100. Like in the previous set of mutual funds, the alpha assumes a small value for the majority of mutual funds and it is not statistically significant. The average beta is lower than on mutual funds presented on annex X, showing that mutual funds that track the FTSE 100 index have significant difficult into track its benchmark and, in this case, only one mutual fund has a beta significant closer to 1, EMIF UK Index Plus B C (Load). Among the set

of mutual funds in analysis, two betas are not statistically significant, the Marks & Spencer UK 100 Companies Acc and Scottish Widows UK Tracker A Acc (see also Figure XIII).

Figure XIII

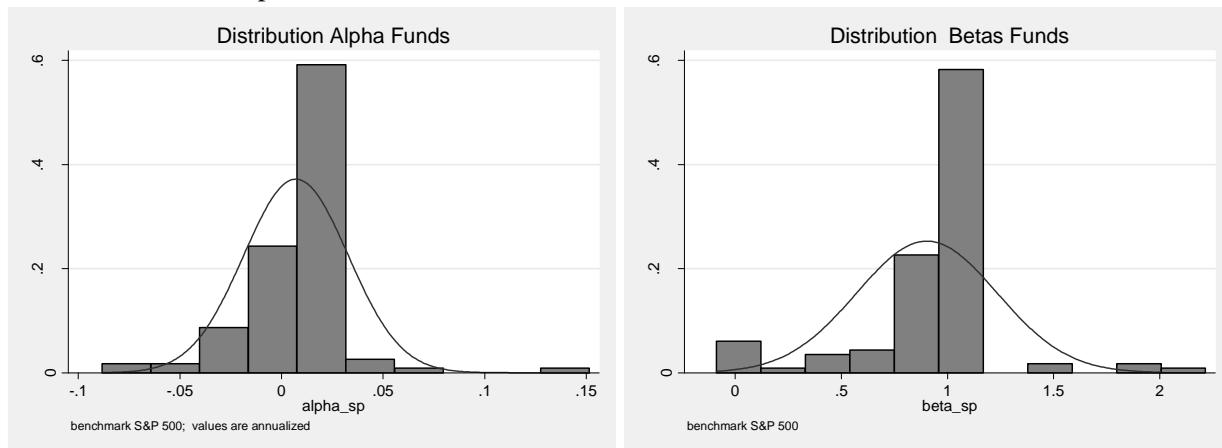

Distribution of Alpha and Beta values for Mutual Funds that have the FTSE 100 as the benchmark

Finally, annex XII, shows information about mutual funds that track the S&P 500. Contrary to ETFs data, the set of mutual funds where the S&P 500 index is the benchmark is the one with the highest sample. The alpha's value is low for commonplace mutual funds and lower, in average, than on the previous two sets of mutual funds in analysis. It is not statistically significant for the majority of mutual funds but in this case we have a larger number of alphas that are statistically significant with 95% confidence level, 44 in 90. The average beta assumes the highest value among the 3 sets of mutual funds in analysis (mutual funds that track the FTSE 100, the Eurostoxx 50 and the S&P 500), 0.96, showing that mutual funds that track the S&P 500 are very efficient into track the bechmark (see also Figure XIV).

Figure XIV

Distribution of Alpha and Beta values for Mutual Funds that have the S&P 500 as the benchmark

On annex VII, VIII and IX we have the results of the tracking error, computed in 3 different ways, for each set of mutual funds, in the same way that I did previously for ETFs. We can conclude that the mutual funds that track the S&P 500 presents, in average, the lowest value for tracking error computation, followed by mutual funds that track the Eurostoxx 50 and finally mutual funds that track the FTSE 100, which lead to the same conclusion of beta's analysis, i.e., mutual funds that have as a benchmark the S&P 500 are, in average, the mutual funds that best track the performance of the benchmark index, followed by Eurostoxx 50 mutual funds and FTSE 100 mutual funds (see also Figure XV, XVI and XVII).

Figure XV

Distribution of tracking errors for Mutual Funds that have the Eurostoxx 50 as the benchmark

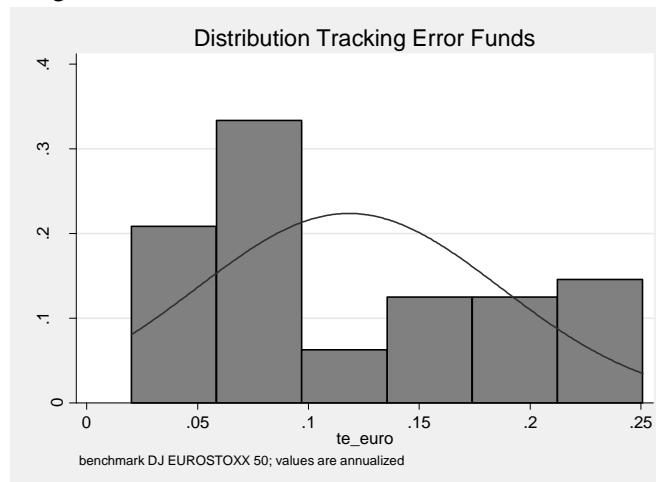

Figure XVI

Distribution of tracking errors for Mutual Funds that have the FTSE 100 as the benchmark

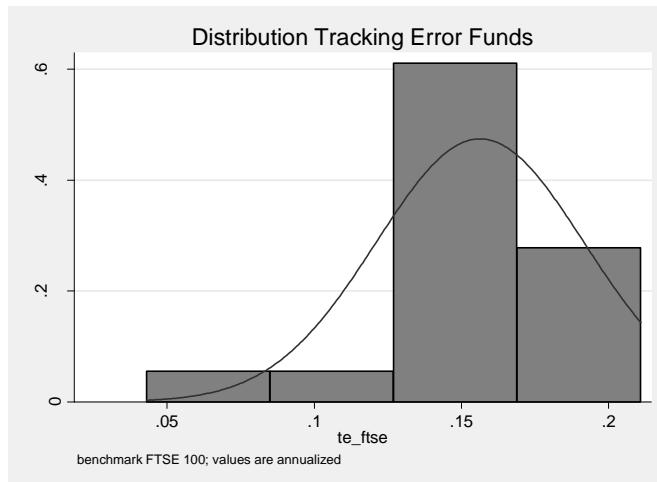

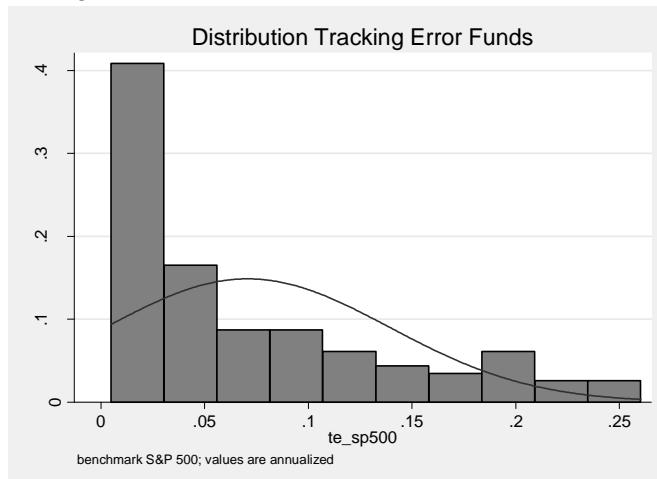

Figure XVII

Distribution of tracking errors for Mutual Funds that have the S&P 500 as the benchmark

ETFs and Mutual Funds

It is important to highlight some conclusions regarding the relation between ETFs and mutual funds in the final of this extensive analysis. First, as the mutual funds are an older investment vehicle than ETFs, they present usually a higher history, so, a larger number of observations. Second, it seems that the ETFs track better their benchmarks than mutual funds do, presenting higher beta and lower tracking error. This is particularly evident when the benchmark is the

FTSE 100. Third, and in spite the lack of information, seems that the majority of mutual funds present higher fees than ETFs, which can be justified by the design of the mutual fund as a financial product.

V. Conclusion

In the final of this paper, we can highlight some of the main conclusions of the study. ETFs seem to track efficiently their benchmarks. Equity index ETFs present positive alphas, while leveraged and inverse ETFs present negative alphas, although hardly statistically significant for both cases. ETFs that track the S&P 500 index, do it more efficiently than ETFs that track FTSE 100 index and Eurostoxx 50 index, the betas are closer to one and the tracking errors are smaller. However, I note that the number of equity index ETFs that track the S&P 500 is reduced due to the dominant position of the SPDR in this specific segment of ETFs (first-mover advantage).

Contrarily the F-test for leveraged and inverse ETFs showed that ETFs that track leveraged and inversely the S&P 500 index have more difficult into meet its objective. Among equity index ETFs, those which track the Eurostoxx 50 present more difficulty into meet its target.

Betas present a large dispersion mainly for ETFs that track FTSE 100 and Eurostoxx 50 which implies that tracking errors are also larger for these ETFs.

Equity index ETFs that have as the benchmark the FTSE 100 index tend to be traded at a premium while those which have the Eurostoxx 50 index as a benchmark tend to trade at a discount. Leveraged and inverse ETFs tend to be traded at a premium. Beta and tracking errors of equity index and leveraged and inverse ETFs are not consistent over time.

The inclusion of the mutual funds in this study allowed me to show that the ETFs in analysis are, in average, more efficient than traditional mutual funds with the same benchmark index, tracking better the target and presenting lower fees.

One last note for the different lifetime of ETFs in analysis, which is justified by the relatively recent history of this type of investment vehicle that made the analysis more difficult and limited more homogeneity among the sample.
